

Module 12 - chapter 11

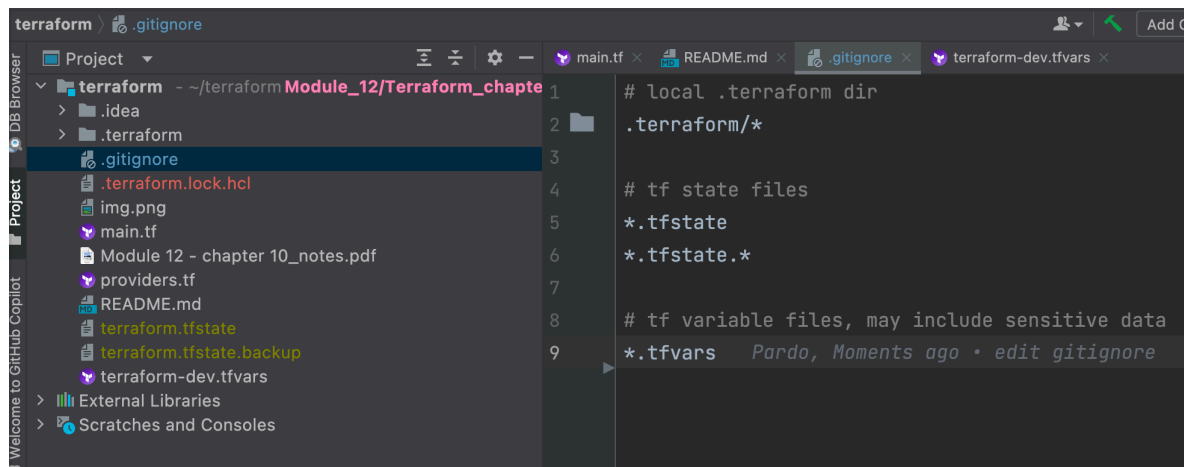

Create Git Repository for local Terraform Project

The project files used in this lecture can be found here:

<https://gitlab.com/twn-devops-bootcamp/latest/12-terraform/terraform-learn>

Create a TF project for our TF project

1. In GitHub create an empty repo
2. -> git init
3. Create a .gitignore in the project

```
1 # local .terraform dir
2 .terraform/*
3
4 # tf state files
5 *.tfstate
6 *.tfstate.*
7
8 # tf variable files, may include sensitive data
9 *.tfvars
```

I need to push '.terraform.lock.hcl' so I removed it from my .gitignore.

terraform.lock.hcl has the list of providers that I have installed locally with specific versions:

```
1 # This file is maintained automatically by "terraform init".
2 # Manual edits may be lost in future updates.
3 provider "registry.terraform.io/hashicorp/aws" {
4   version = "6.8.0"
5   constraints = ">= 6.0.0, <= 6.0"
6   hashes = [
7     "h1:8f1s9dFT/Dq3tYB2X+Q3qR+x7TNwPsdANP7rLt0sv0=",

23  ]
24 }
```

So that all team members have the same version of the providers - no version diffs locally

4. Link local repo with remote repo -> git remote add origin git@github.com:AstridCaballero/Module_12_Terraform.git
5. Commit changes
6. Push to remote repo -> git push -u origin Module_12/
